

L5: Communication for organization: how cellular conversations sculpt organ-scale structures.

By the end of this lecture, you should be able to:

- Define the term 'weak emergence' in a biological context.
- Describe the main events in development of the mammalian kidney.
- Use experimental evidence to demonstrate that renal development is regulative, and not just the realization of an inflexible 'genetic blueprint'.
- Describe how cell-cell signalling achieves population balance, quorum sensing, patterning of an epithelial tree and correct vascular development
- Demonstrate that these signalling systems allow automatic correction of developmental errors.
- Identify examples of the organizational principles above in organization at smaller scales (within cells), and at much larger scales (within super-organisms and societies).

The problem:

How do cells, about 10 μ m across and that can sense conditions only within themselves and at their surfaces, cooperate to make an organ 10cm across (10,000 x their length)?

Possible solution 1: precise working out of a 'genetic blueprint' / 'program' / 'recipe'

Possible solution 2: adaptive self-organization

(Some philosophers talk about another form, 'strong' emergence – this is essentially irrelevant to science)

('weak') EMERGENCE – the presence of properties at system-level that are not present at component level.

Homely examples:

A radio works because its components are arranged in a particular way – not because any one of them has 'radio reception' as a property.

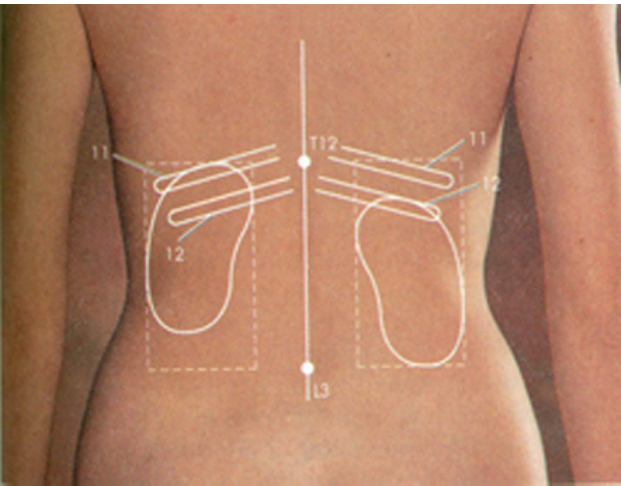

Pressure/ temperature of a gas are not properties of individual molecules

There is nothing 'special' about development of the kidney – we are using it as an example organ and the same basic messages would have appeared had we used any other organ.

"To see a World in a Grain of Sand
And a Heaven in a Flower,
Hold Infinity in the palm of your hand
And Eternity in an hour."

The star of this lecture: the kidney

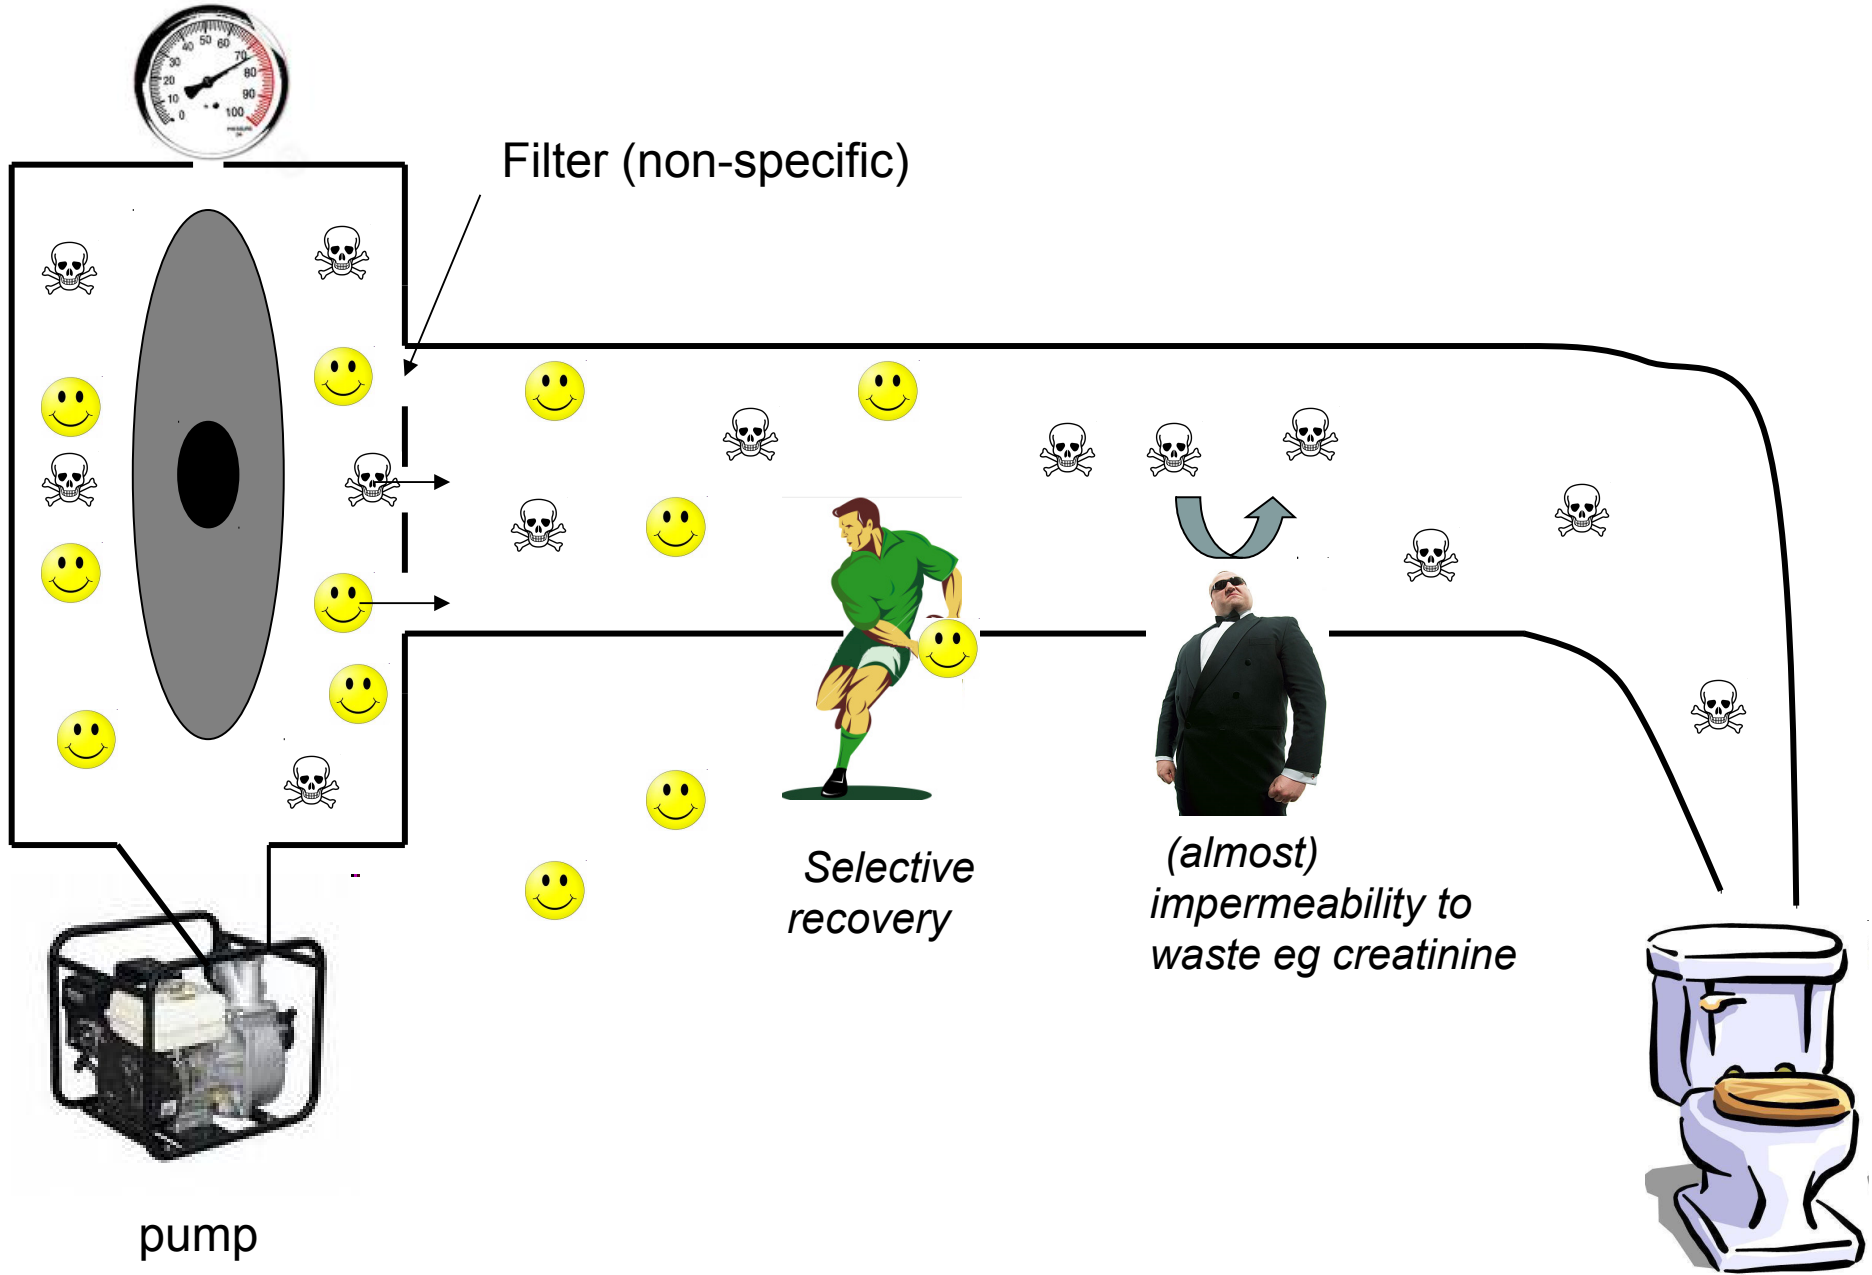

20% of cardiac output

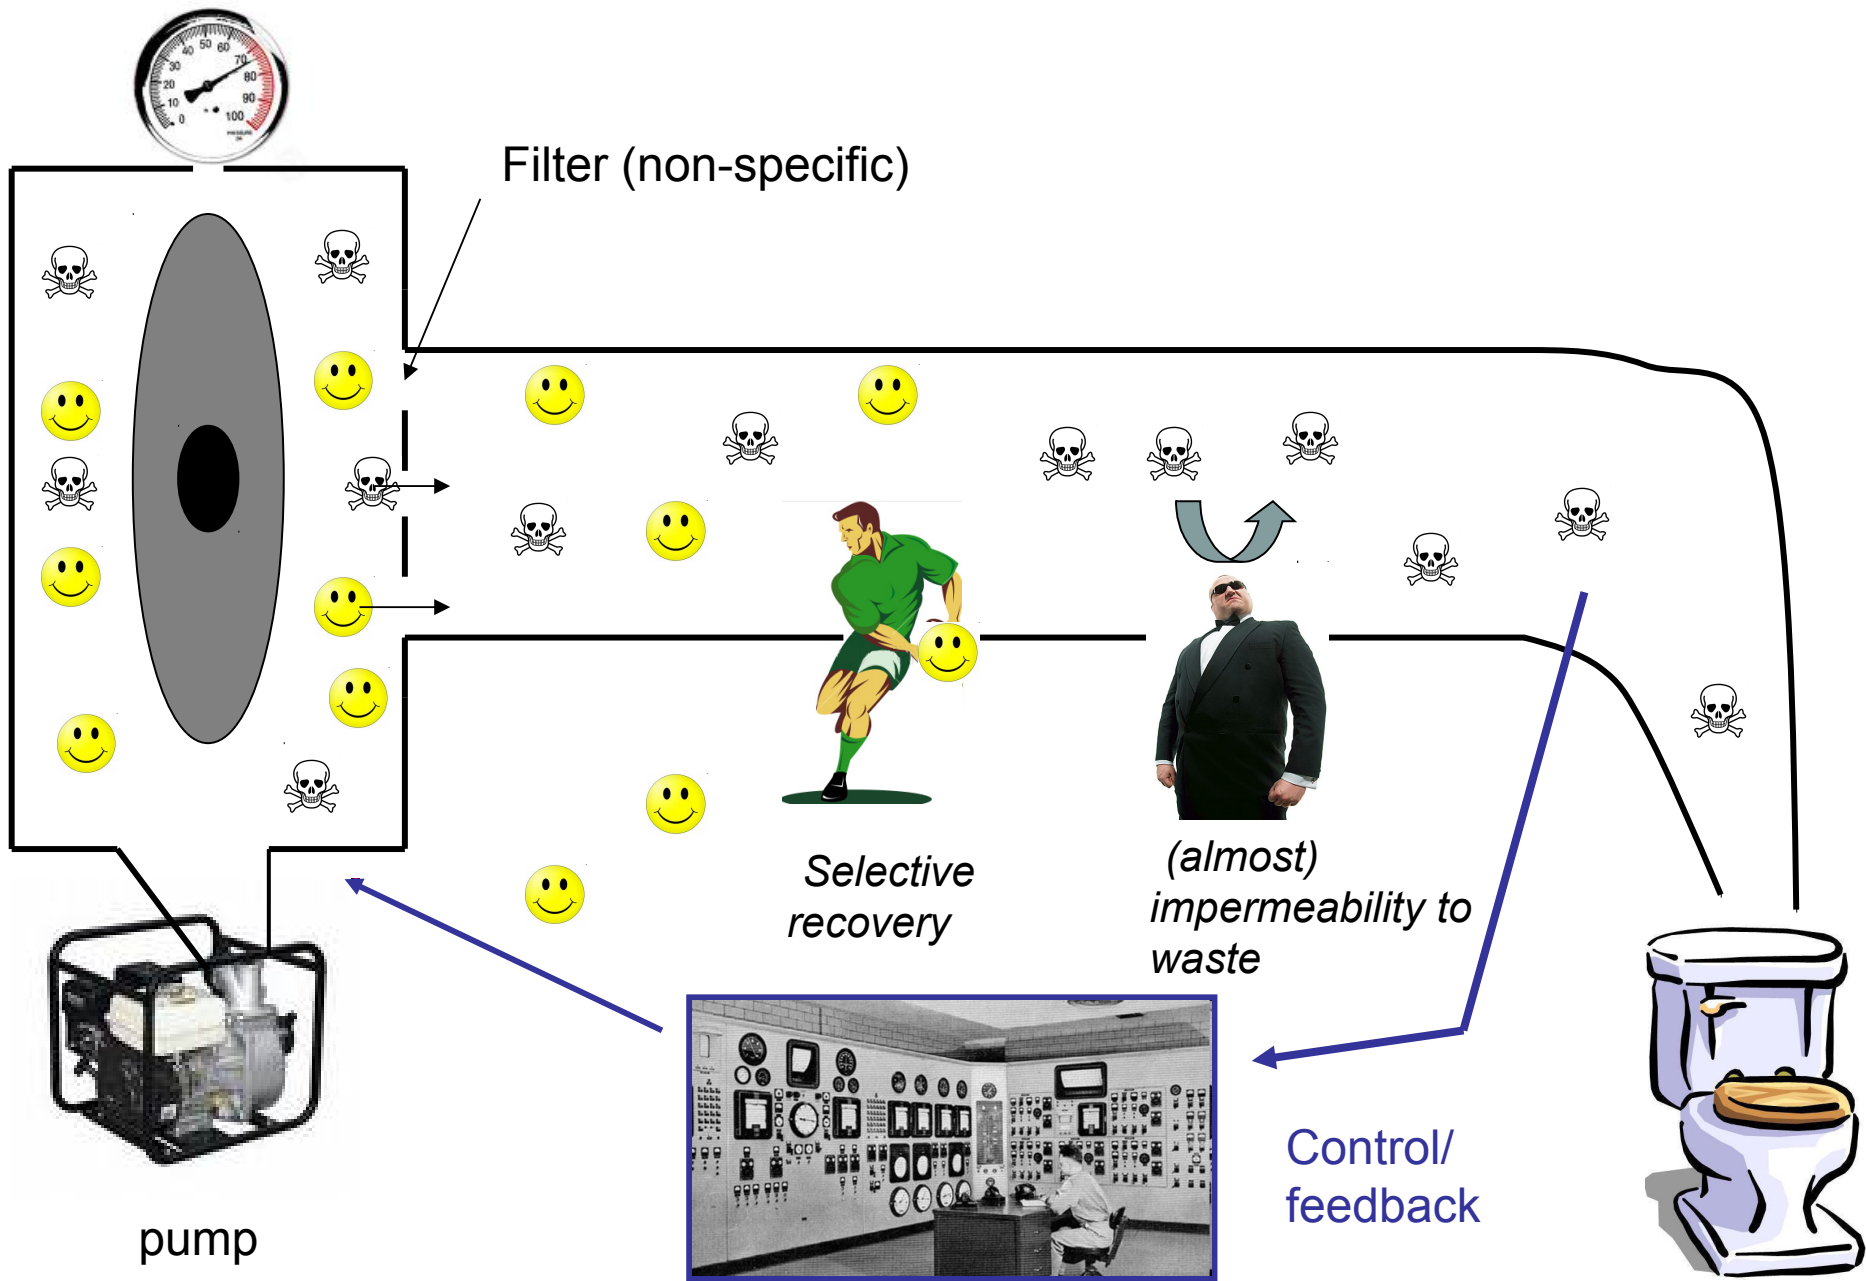

Left kidney

TS17 Urogenital System

Problem 1: how to make just one ureter come out of each Wolffian duct:

Solution: a load of biochemical 'No Entry' signs where ureters are not wanted

This is what the kidney area looks like just after the bud has entered the mesenchyme

In this picture, red marks the nuclei of all cells while green stains only cells of the ureteric bud.

Branching of the ureteric bud

Problem 2 – how is the branching controlled?

1) GUESS that surrounding cells make signals that control the branching

conjecture

1) GUESS that surrounding cells make signals that control the branching

2) LOOK for signal proteins and matching receptors that are in the right place for this

Receptor (Ret)

Co-receptor (GFR1a)

Signal (GDNF)

Actual binding of radioactive GDNF

1) GUESS that surrounding cells make signals that control the branching

2) LOOK for signal proteins and matching receptors that are in the right place for this

3) TEST to see if they control the bud

conjecture

Refutation (or provisional acceptance)

1) GUESS that surrounding cells make signals that control the branching

2) LOOK for signal proteins and matching receptors that are in the right place for this

3) TEST to see if they control the bud

Interrupt the signal

Give a fake signal

conjecture

Refutation (or provisional acceptance)

Interrupt the
signal:

Control (irrelevant) antibody

anti-GDNF

Make our own message and see if the cells respond:

Inducing branches from the very early tube

Attracting branches from established tubes.

More signals have been discovered using the same approach:

(Signals colour-coded according to source tissue)

Problem 3: how do the branches of the tree avoid getting tangled?

A model of self-loathing:

Model:

UB secretes a substance called 'horrid' – a noise component is also added

UB tips always grow in the direction of least [horrid]

UB branches (1 tip → 2 adjacent ones) if [horrid] < threshold

(everything is sensed only locally, in the pixels immediately adjacent to each cell's own pixel)

Anatomy

[Horrid]

To chase the molecular basis, we need an easier assay: attempted collision.

Real

Experimental method:

Culture kidneys aimed at one another

Experimental method:

Culture kidneys aimed at one another

Add various test drugs (ideally ones that hit whole classes of signalling molecules)

Experimental method:

Culture kidneys aimed at one another

Add various test drugs (ideally ones that hit whole classes of signalling molecules)

Hope to see a crash.

Third Department of Internal Medicine, Kumamoto University School of Medicine, Kumamoto 860, Japan

Normal

Congested large vessels,
'empty' glomeruli

Model: developing glomeruli produce VEGF that attracts blood vessels.

SUMMARY of the kidney story (not quite the end of the lecture)

Ureteric bud emergence from WD depends on balance of permissive (GDNF) and inhibitory (BMP4) signals from other tissues.

Branching of ureteric bud is encouraged by positive signals (GDNF) from 'virgin' metanephrogenic mesenchyme and discouraged by negative signals (BMP2, TGF β) from nephron-forming areas.

Branches space out by self-loathing (secreting BMP7)

Nephrons form in response to Wnt9b from branch tips

Pre-nephron aggregates sense their size by autocrine Wnt4

Developing glomeruli secrete VEGF to attract blood vessels.

In this way, the whole system is adaptive and self-corrective, and cells can make something much larger than themselves.

THERE IS STILL VERY MUCH THAT WE DO NOT UNDERSTAND

The Bottom line: the organ organizes itself cells exchanging simple messages with their neighbours, in a biochemical code.

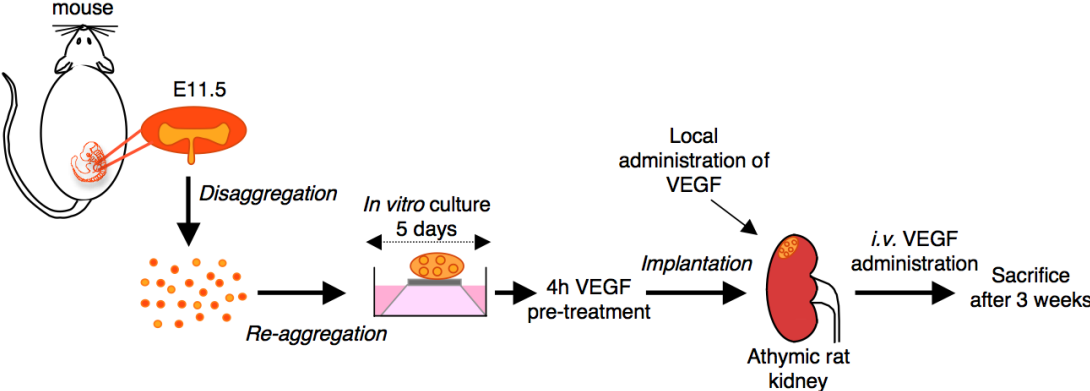

(ignore the arrow)

(Off-syllabus tangent; we can *use* our knowledge of cell-cell communication to engineer replacement organs)

Mathieu Unbekandt, Veronica Ganeva.

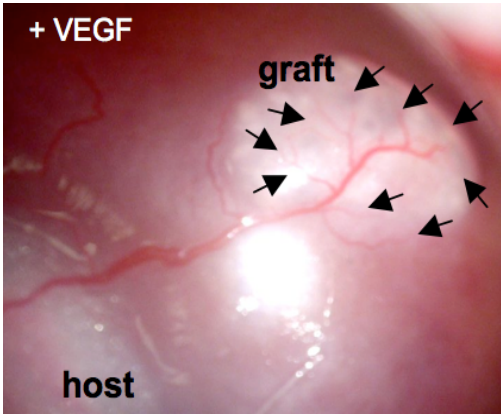

With our colleagues in Italy, we have tested these kidneys in rats:

Grafting

After some weeks

i.v. injection of fluorescent SA

SA turns up in prox tubule

CLOSING REMARKS – CAN WE DRAW 'BIGGER' CONCLUSIONS?
